Abstract

This paper describes the development of a holonomic robot using omni directional wheels. Both a development of the kinematic and dynamical equations of motion are derived and used as a foundation for gaining further insight into the capabilities of the robot. A discussion of the vision system used to detect objects and obstacles during navigation.

1 Variables

Parameter	Units	Description
R	m	robot radius
M	kg	mass of robot
I	$kg \cdot m^2$	inertia of robot
I_w	$kg \cdot m^2$	inertia of wheel
a_i	m/sec^2	acceleration in the i^{th} direction
v_i	m/sec	velocity in the i^{th} direction
ω_i	rad/sec	i^{th} wheel speed
r_w	m	wheel radius
τ_i	$N \cdot m$	wheel torque
F_i	N	traction force (vector)
f_i	N	magnitude of traction force ($\ F_i\ $)

2 Introduction

Robots come in a variety of types and configurations: wheeled, tracked, legs, flying, etc. Common wheeled robots typically have two wheels (directly driven) with a caster wheel to make the robot stable. There are some without the caster wheel and employ a control system to keep them upright (inverted pendulum problem) and resemble a Segway scooter. All of these two wheeled robot are non-holonomic systems.

Definition 1 *A non-holonomic system in physics and mathematics is a system whose state depends on the path taken to achieve it. An automobile is an example of a non-holonomic vehicle. The vehicle has three degrees of freedomits position in two axes, and its orientation relative to a fixed heading. Yet it has only two*

Figure 1: Holonomic soccer robot using 4 omni directional wheels and a kicking motor used to hit the red ball into a goal. [1].

Figure 2: Omni directional wheel used on the soccer robot which allows movement in any direction.

controllable degrees of freedom acceleration/braking and the angle of the steering wheel with which to control its position and orientation. [9]

Due to these constraints, a holonomic robot (**Figure 4**) which could travel in any direction and immediately change its position and orientation is much more desirable. There are a variety of different wheels which make this type of robot possible such as mecanum or omni wheels (**Figure 2**).

Omni wheels operate like standard wheels in that the force is produced normal to the motor's axis of rotation and as a result of friction. However, there are a series of smaller wheels which ring the main wheel and allow the wheel to slip in the direction of the motor rotational axis. Note that no force is produced parallel to the motor axis, just slippage.

3 Holonomic Dynamics

The dynamics for a holonomic robot, such as **Figure 4**, with 4 omni directional wheels (see **Figure 2**, can be derived using Euler-Lagrangian (\mathcal{L}) which defines a system's kinetic (T) and potential (V) energies in relation to a set of generalized coordinates (q) and generalized forces (Q):

$$\mathcal{L} = T - V \quad (1)$$

$$\frac{d}{dt} \left\{ \frac{\partial \mathcal{L}}{\partial \dot{q}} \right\} - \frac{\partial \mathcal{L}}{\partial q} = Q \quad (2)$$

$$T = \frac{1}{2}M(\dot{x}^2 + \dot{y}^2) + \frac{1}{2}J\dot{\psi}^2 + \frac{1}{2}J_w(\dot{\theta}_1^2 + \dot{\theta}_2^2 + \dot{\theta}_3^2 + \dot{\theta}_4^2) \quad (3)$$

$$V = 0 \quad (4)$$

However, the dynamics must be calculated from an inertial reference frame (W) and take into account the rotating body frame dynamics (B'). Now, assume the body frame is offset from the center of mass (CM) by x_m and y_m which compose a vector r_m . Thus the velocity of the robot in the rotating frame would be:

$$F_x = M(\ddot{x} - 2\dot{\psi}\dot{y}) \quad (13)$$

$$F_y = M(\ddot{y} + 2\dot{\psi}\dot{x}) \quad (14)$$

$$T = J\ddot{\psi} \quad (15)$$

$$\tau_w = J_w\ddot{\theta}_1 \quad \tau_w = J_w\ddot{\theta}_2 \quad \tau_w = J_w\ddot{\theta}_3 \quad \tau_w = J_w\ddot{\theta}_4 \quad (16)$$

$$\begin{bmatrix} F_x \\ F_y \\ T \end{bmatrix} = \begin{bmatrix} M & 0 & 0 \\ 0 & M & 0 \\ 0 & 0 & J \end{bmatrix} \begin{bmatrix} \ddot{x} \\ \ddot{y} \\ \ddot{\psi} \end{bmatrix} + \begin{bmatrix} 0 & -2M\dot{\psi} & 0 \\ 2M\dot{\psi} & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} \dot{x} \\ \dot{y} \\ \dot{\psi} \end{bmatrix} = \mathcal{M}\ddot{X} + \mathcal{O}\dot{X} \quad (17)$$

3.0.1 World Coordinates

Now the dynamics derived so far are all in the body frame and we could stop here and develop a controller which performs velocity control. However, position control is more useful and a transform needs to be performed to move the velocities and accelerations into the world frame.

$$\dot{X}^W = R_B^W \dot{X}^B \quad (18)$$

$$R_B^W = \begin{bmatrix} \cos \psi & \sin \psi & 0 \\ -\sin \psi & \cos \psi & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (19)$$

$$\ddot{X}^W = \dot{R}_B^W \dot{X}^B + R_B^W \ddot{X}^B \quad (20)$$

$$R_B^W = \begin{bmatrix} \sin \psi & -\cos \psi & 0 \\ \cos \psi & \sin \psi & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (21)$$

Now, substituting this into the dynamics, gives:

$$F = \mathcal{M}(\dot{R}\dot{X} + R\ddot{X}) + \mathcal{O}R\dot{X} \quad (22)$$

$$F = \mathcal{M}R\ddot{X} + (\mathcal{M}\dot{R} + \mathcal{O}R)\dot{X} \quad (23)$$

3.0.2 External Forces and Torques

Now looking at figure 4 and summing the forces into their body referenced x and y directions and the torque about the z axis, gives us:

$$\sum F_x = f_1 \sin(\phi) - f_2 \sin(\phi) - f_3 \sin(\phi) + f_4 \sin(\phi) \quad (24)$$

$$\sum F_y = f_1 \cos(\phi) + f_2 \cos(\phi) - f_3 \cos(\phi) - f_4 \cos(\phi) \quad (25)$$

$$\sum T = L(f_1 + f_2 + f_3 + f_4) \quad (26)$$

Additionally, we can simplify this by assuming all of the angles are the same (e.g., $\phi_1 = \phi_2 = \phi_3 = \phi_4$) and can now put this into a matrix form:

$$\begin{bmatrix} F_x \\ F_y \\ T \end{bmatrix} = \begin{bmatrix} \sin(\phi) & 0 & 0 \\ 0 & \cos(\phi) & 0 \\ 0 & 0 & L \end{bmatrix} \begin{bmatrix} 1 & -1 & -1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} f_1 \\ f_2 \\ f_3 \\ f_4 \end{bmatrix} \quad (27)$$

where ϕ is again the angle of the motors as defined in **Figure 4**, f_i is the magnitude of the force produced by the motors, and L is the radius of the robot.

where $\text{pinv}()$ ¹ is defined as the pseudoinverse since $A(\phi)$ is not a square matrix. Finally, substituting these into the original equation, we can calculate the torques given the desired accelerations.

$$\begin{bmatrix} \tau_1 \\ \tau_2 \\ \tau_3 \\ \tau_4 \end{bmatrix} = \frac{Mr_w}{4} \begin{bmatrix} -1 & 1 & 1 \\ -1 & -1 & 1 \\ 1 & -1 & 1 \\ 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} \frac{1}{\sin(\phi)} & 0 & 0 \\ 0 & \frac{1}{\cos(\phi)} & 0 \\ 0 & 0 & \frac{1}{2} \end{bmatrix} \begin{bmatrix} a_x \\ a_y \\ R\dot{\omega} \end{bmatrix} \quad (28)$$

Now looking at this equation, we notice that ϕ can not be equal to 0, 90, 180, 270, or 360 otherwise we get a singularity in the $A(\phi)$ matrix. This however is not an issue in the real world, since the motors would occupy the same physical space and the robot would essentially only have 2 and not 4 motors.

4 Holonomic Robot Kinematics

Now performing a similar exercise for what was done with the dynamics, looking at **Figure 3**, the velocity of motor 1 is given by $v_1 = -\sin(\phi)v_x + \cos(\phi)v_y + R\omega$. Performing this for each wheel gives:

$$\begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \end{bmatrix} = \begin{bmatrix} -\sin(\phi) & \cos(\phi) & L \\ -\sin(\phi) & -\cos(\phi) & L \\ \sin(\phi) & -\cos(\phi) & L \\ \sin(\phi) & \cos(\phi) & L \end{bmatrix} \begin{bmatrix} v_x \\ v_y \\ \omega \end{bmatrix} = \begin{bmatrix} -1 & 1 & 1 \\ -1 & -1 & 1 \\ 1 & -1 & 1 \\ 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} \sin(\phi) & 0 & 0 \\ 0 & \cos(\phi) & 0 \\ 0 & 0 & L \end{bmatrix} \begin{bmatrix} v_x \\ v_y \\ \omega \end{bmatrix} \quad (29)$$

Now setting ω to zero and calculating only linear movement, we can determine the number of equivalent motors as shown in **Figure 5**. For example, setting ϕ to 30° (the red line in **Figure 5**) and traveling in the x direction only ($[v_x \ v_y \ \omega]^T = [1 \ 0 \ 0]^T$), the above equation simplifies to $4\sin(30)$ or 2 equivalent motors. Repeating for the y direction results in $4\cos(30)$ or 3.46 equivalent motors.

Now it is interesting to note that when ϕ is set to 30°, the robot has more equivalent motors when going forward or backwards, while a ϕ of 60° provides more equivalent motors moving left or right. When the motors are are angled at 45°, movement is clearly equally optimized for both forward/backwards and left/right ($2\sin(45)$ is 2.83 motors) movement.

Figure 5 tells us that no matter how the 4 motors are oriented in a realistic configuration, the robot will never have the equivalent use of all 4 motors. Movement in one direction or another can be optimized, but then a sacrifice is made in another direction. This fact is intuitively obvious.

Another issue is these results are also ideal. This logic assumes that the wheels will not slip and have good traction in any orientation. Unfortunately real world results do not mimic this situation and the robot's performance will be reduced.

¹Pseudoinverse: for $m > n$: $A_{left}^{-1} = (A^T A)^{-1} A^T$ or $m < n$: $A_{right}^{-1} = A^T (A A^T)^{-1}$ such that $A A^{-1} = I$ or $A^{-1} A = I$

Figure 4: Configuration of three groups of motors where ϕ is 30, 45, and 60 degrees.

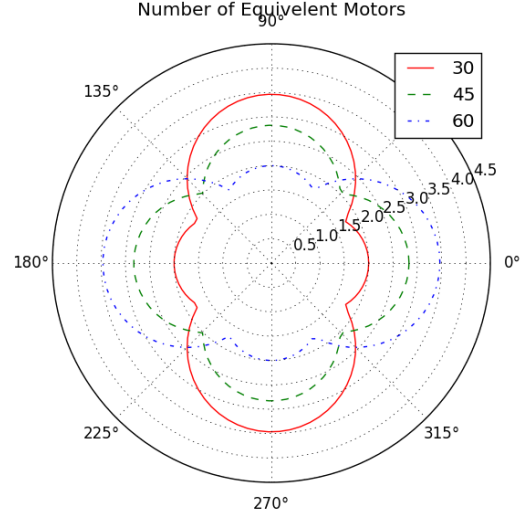

Figure 5: Number of equivalent motors for any direction under linear movement only, no rotational movement allowed.

5 Control

Looking at the state space equations, the system is controllable but it is not observable. Using an IMU (accelerometer, gyro, and magnetometer), the heading (θ) can be determined from the magnetometer and the angular rate (ω) can be determined from the gyro. An observer must be used to estimate the position and velocity of the robot.

Typically encoders attached to the wheels (under the assumption of no slip) would be used to estimate velocity and position. However, with omni wheels, this is not possible since they rely on slippage in order to achieve holonomic motion. Wheel encoders can be useful for detecting excessive amounts of wheel slippage [2] in order to optimize movement or detect failed motors.

6 Guidance and Navigation

In order to have the robot go from one location to another, the position and velocity must be estimated. A Kalman filter using the dynamic equations above will provide this solution. The general form of the Kalman filter can be found in any text book on estimation [11] and have the form:

$$\dot{x} = ax + bu \quad (30)$$

$$\tilde{x} = \hat{x} - x \quad (31)$$

where the error (\tilde{x}) is the difference between the estimated state (\hat{x}) and the true state (x).

A Full Derivation of EOM

A.1 EOM

hi how are you

B Robot Hardware

The robot is teleoperated from a laptop via a bluetooth link to an Arduino microcontroller which runs the motor drivers and sensors.

B.0.1 MiniIMU

B.0.2 Camera

C Robot Software

C.0.3 OpenCV

The vision system uses the Open Computer Vision (OpenCV [8]) is used to track the ball and guide the robot to the ball (visual servoing).

Figure 6: IMU.

Figure 7: The software architecture composed of ROS nodes.

The BGR (blue, green, red) image is transformed to the HSV (hue, saturation, and value) system to help account for variable lighting conditions.

Hue The "attribute of a visual sensation according to which an area appears to be similar to one of the perceived colors: red, yellow, green, and blue, or to a combination of two of them"

Saturation The "colorfulness of a stimulus relative to its own brightness"

Value, Lightness The "brightness relative to the brightness of a similarly illuminated white"
